MTBF CALCULATION – FLUX DRIVE

The following is the procedure to calculate **MTBF** (Mean Time Between Failure), and to determine **FIT** (Estimated Failure Rate: 10⁻⁹/HR) for inverters.

1. To determine **FIT**:

Given: The number of units under consideration, the number of failures, and the number of hours per year (10,000 used for simplicity).

Total Hours of Operation = Number of Units x Hours per Year (eq. 1)

 $Failure Rate = \frac{Number of Failures}{Total Hours of Operation} (eq. 2)$

FIT = $10^9 \times Failure Rate (eq. 3)$

2. To determine **MTBF**:

Hours per Failure = $\frac{1}{Failure Rate}$ (eq. 4)

Rearranging (eq. 3):

Failure Rate = FIT x
$$10^{-9}$$
 (eq. 5)

Substituting (eq. 5) into (eq. 4), we obtain:

Hours per Failure = $\frac{1}{\text{FIT x 10^{-9}}} = \frac{10^9}{\text{FIT}}$ (eq. 6)

 $MTBF = \frac{Number of Failures}{Total Hours of Operation} (eq. 7)$

Actual Hours per Year = 24 hours/day x 365 days/year = 8,760 hours/year (eq. 9)

Substituting (eq. 6) and (eq. 9) into (eq. 7), we obtain:

MTBF = $\frac{10^9}{\text{FIT x 8 760}}$ (eq. 10)

3. Example Calculation:

Given:

15 failures 10,000 units under evaluation

Total Hours of Operation = Number of Units x Hours per Year = 10,000 x 10,000 = 10⁸ Hours Failure Rate = <u>Number of Failures</u> Total Hours of Operation = $\frac{15}{10^8}$ = 1.5 x 10⁻⁷ Failures per Hour FIT = 10⁹ x Failure Rate = 10⁹ x 1.5 x 10⁻⁷ = 150 FIT MTBF = $\frac{10^9}{\text{FIT x 8,760}}$ = $\frac{10^9}{150 \times 8,760}$ = 761 MTBF

Therefore, if an installation had 200 inverters, 0.26 random failures per year could be expected:

$$(\frac{200}{761} = 0.26)$$
